

UNIT 1 – CHAPTER 7 STUDENT NOTES: ATOMIC STRUCTURE AND PERIODICITY

Atomic Model

Max Planck – discovered that matter is lost or gained in whole-number multiples

$$E = h\nu$$

E = energy (Joules)

h = Planck's constant (6.63×10^{-34} J-sec)

ν = frequency (Hz) (waves/sec)

Electromagnetic radiation – form of energy emitted by matter

All electromagnetic radiations travel at the speed of light and follow the formula:

$$c = \lambda \cdot \nu \quad c = 3.0 \times 10^8 \text{ m/sec}$$

λ = wavelength
 ν - frequency

Energy of electromagnetic radiation:

$$E = h\nu, E = \frac{h \cdot c}{\lambda}$$

EX 1: The blue color in fireworks is often achieved by heating copper (I) chloride (CuCl) to about 1200°C . Then the compound emits blue light having a wavelength of 450nm. What is the increment of energy (the quantum) that is emitted at 4.50×10^2 nm by CuCl ?

$$E = h \cdot \nu \rightarrow E = \frac{h \cdot c}{\lambda}$$

$$E = \frac{(6.63 \times 10^{-34} \text{ J} \cdot \text{sec}^{-1}) (3.0 \times 10^8 \text{ m/sec})}{(4.50 \times 10^{-7} \text{ m})}$$

$$E = 4.41 \times 10^{-19} \text{ J} \text{ or } 4.41 \times 10^{-22} \text{ KJ}$$

PLANCK'S CONSTANT:
 $h = 6.63 \times 10^{-34} \text{ J/SEC}$

EX 2: It takes 208.4 kJ of energy to remove 1 mole of electrons from an atom on the surface of rubidium metal. How much energy does it take to remove a single electron from an atom on the surface of solid rubidium? What is the maximum wavelength of light capable of doing this? What color range would this be?

$$a) \frac{208.4 \text{ kJ}}{\text{mol}} \times \frac{1 \text{ mol}}{6.02 \times 10^{23} \text{ particles}} = 3.46 \times 10^{-22} \text{ kJ/particles} \text{ or } 3.46 \times 10^{-19} \text{ J/particles}$$

$$b) E = \frac{h \cdot c}{\lambda} \rightarrow 3.46 \times 10^{-19} \text{ J} = \frac{(6.63 \times 10^{-34} \text{ J}\cdot\text{s})(3.0 \times 10^8 \text{ m/s})}{\lambda}$$

$$\lambda = 5.73 \times 10^{-7} \text{ m} \rightarrow \text{GREEN LIGHT}$$

Albert Einstein – developed the formula

$$E = mc^2$$

which proved waves should have mass

Louis de Broglie – asked the question: Do particles have wave properties?

$$\text{If: } m = \frac{h}{(\lambda \cdot \text{velocity})}$$

m - kg

h – Planck's constant (J/Hz)

velocity – m/sec

λ - meters

$$\text{Then: } \lambda = \frac{h}{(m \cdot \text{velocity})}$$

Small objects (e⁻) have large wavelengths

Large objects (bowling balls) have small wavelengths

EX 3: Compare the wavelength for an electron (mass = 9.11×10^{-31} kg) traveling at a speed of 1.0×10^7 m/sec with that for a ball (mass = 0.10 kg) traveling at 35 m/sec.

$$\lambda = \frac{h}{m \cdot v}$$

ELECTRON
 MASS = 9.11×10^{-31} kg
 SPEED = 1.0×10^7 m/sec

$$\lambda = \frac{(6.63 \times 10^{-34})}{(9.11 \times 10^{-31} \text{ kg})(1.0 \times 10^7)}$$

$$\lambda = 7.28 \times 10^{-11} \text{ m}$$

BALL
 MASS = 0.10 kg
 SPEED = 35 m/sec

$$\lambda = \frac{(6.63 \times 10^{-34})}{(0.10 \text{ kg})(35 \text{ m/sec})}$$

$$\lambda = 1.9 \times 10^{-34} \text{ m}$$

$\therefore$ BALL HAS MUCH SMALLER λ THAN e⁻

Neils Bohr – developed the quantum model of the atom.

- Quantum model – proposed that the electrons in a hydrogen atom move around the nucleus only in certain allowed circular orbits.
- Classical physics said as an electron circles an atom, it is accelerating because it is changing direction and a charged particle (e^-) should lose energy and fall into the nucleus. Bohr said an electron loses energy as it moves from level to level.

$$E_{\text{Electron}} = -\frac{R_H}{n^2} \quad R_H = \text{RYDBERG CONSTANT} \rightarrow 2.179 \times 10^{-18} \text{ J}$$

EX 4: Calculate the energy evolved as an excited atom has an electron fall from $n = 2$ to $n = 1$. Calculate the wavelength of energy and the type of radiation needed to do this.

$$E = -\frac{R_H}{n^2}$$

$$1) E = (-2.179 \times 10^{-18} \text{ J}) \left(\frac{1}{(1)^2} - \frac{1}{(2)^2} \right) = \boxed{-1.63 \times 10^{-18} \text{ J}}$$

INDICATES J GIVEN OFF

$$2) E = \frac{h \cdot c}{\lambda} \rightarrow 1.63 \times 10^{-18} \text{ J} = \frac{(6.63 \times 10^{-34}) (3.0 \times 10^8)}{\lambda}$$

$$1.63 \times 10^{-18} = \frac{1.989 \times 10^{-25}}{\lambda}$$

$$\boxed{\lambda = 1.22 \times 10^{-7} \text{ nm}}$$

END 1.1

BEGIN 1.2

Electron configurations – model used to explain the electron arrangement of the atom.

- Shell – an area where the electrons are located
- Subshell – the shape of the area of the electrons
- Orbital is a position in a subshell

EX 5: Draw electron configurations for the following atoms:

K

Sn

24pt
28pt

47pt
61pt

46pt
60pt

EX 6: Draw electron configurations for the following ions (atoms with a charge):

Ca

Se $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^4$ - Atom (Se^{-2})
 $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6$ - Ion

Al $1s^2 2s^2 2p^6 3s^2 3p^1$ - Atom (Al^{+3})
 $1s^2 2s^2 2p^6 3s^0 3p^0$ - Ion

Cl

Quantum numbers

Principle quantum number (n): 1, 2, 3, 4... = shell

Angular quantum number (l): 0 to n-1 = subshell

s = 0, p = 1, d = 2, f = 3

Magnetic spin quantum number (m_l): = position in the orbital

s = 0

p = -1, 0, 1

d = -2, -1, 0, 1, 2

f = -3, -2, -1, 0, 1, 2, 3

Spin quantum number (s): +1/2 or -1/2 = spin of the electron

Pauli exclusion principle:

Br (Bromine) Atomic #35, Mass #80

Electron configuration notation:

$1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^5$

Orbital notations:

	n	l	m _l	s
1s ²	1	0	0	+1/2 -1/2
2s ²	2	0	0	+1/2 -1/2
2p ⁶	2	1	-1 0 +1 -1 0 +1	+1/2 +1/2 +1/2 -1/2 -1/2 -1/2

EX: Assign quantum numbers for **ALL** the electrons in the Neon atom.

Ne: 1s²2s²2p⁶

END 1.2

BEGIN 1.3

PERIODICITY: The chemical and physical properties of atoms are periodic functions of their atomic number.
